

Overview on the Database Schema of Process Mining

The analytical database of **Scheer PAS Process Mining** is composed by two parts:

- some work tables only used during the ETL process and
- public tables that can be queried by any kind of analytic service to display meaningful data.

Public Schema: Snowflake Schema

The public schema of the analytical database is a [snowflake schema](#). That means that there are fact tables representing the instances (names starting by **Fact_**) and dimension tables representing the data (names starting by **Dim_**). It is a snowflake and not a simple star, because there are relations between the facts.
