

classToXML

Syntax	<pre>set aBlob = anObject.classToXML() set aBlob = anObject.classToXML(options)</pre>																												
Semantics	<p>The operation takes any object (<code>anObject</code>) and tries to map it to an XML document. The document structure is given by the class definition of <code>anObject</code>. If this is not possible an error is raised (e.g. XML parser errors, invalid mappings, etc.).</p> <p>By default the following mapping rules apply:</p> <ul style="list-style-type: none">• Class attributes are mapped to XML attributes.• Association ends are mapped to XML elements. <p>These default rules can be overridden by using the stereotypes XMLElement, XMLAttribute, and XMLCharacter on class properties.</p> <p>More about these mapping rules, stereotypes and tagged values (e.g. for number and date & time formatting) can be found on Controlling the XML Serialization With Stereotypes.</p> <div><p>A conversion with operation <code>classToXML()</code> always returns an object of type Blob. To display this data as a String you need to transcode it first (see transcodeToString() Operation).</p></div>																												
Substitutables	<div><div>a n O b j e c t</div><div>Target object can be any complex object. However, simple types and arrays are not supported, since they do not map naturally to a well formed XML document.</div></div> <div><div>o p t i o n s</div><div><p><code>xmlToClass()</code> offers an optional parameter of type XMLComposeOptions.</p><div><div>XMLCompseOptions</div><div><div>+prolog : String [0..*] +timezone : String [0..1] +dateFormatString : String [0..1] = %F +encoding : String [0..1] = UTF8 +rootName : String [0..1] +rootNamespace : String [0..1]</div></div></div><p>Its attributes are:</p><table><tr><th>Attribute</th><th>Type</th><th>Description</th><th>Example</th></tr><tr><td>prolog</td><td>Array of String</td><td>The string values are inserted right before the root element of the generated document. XML Serialization Example

Assume you have an object `myAddress` of type `Address`.

The following action script serializes this object.

```
set xmlBlob = myAddress.classToXML();
```

The sample XML document below illustrates the mapping executed by `classToXML()`. The object **myAddress** of type **Address** is mapped to an XML document as depicted in the following XML document:

```
<myAddress id="myAddressID">
  <street>108, Kearny Avenue</street>
  <city>Newark</city>
</myAddress>
```

Note, that the XML element **myAddress** is of type **Address**. This type has the attribute **id**, which corresponds to the XML attribute **id**. Additionally, the XML elements **street** and **city** are mapped to the association ends **city** respectively **street**. Both are having the type **String**.
