capture

Syntax	`set aStringArray = aString.capture(aRegExPattern)`	
Semantics	Returns a list of all captured groups that are identified by the regular expression.	
Substitutables	`aString`	Can be any variable or object attribute having the type **String**.
	`aRegExPattern`	A variable or a literal containing a valid regular expression defining groups within `aString`.
	`aStringArray`	An array of **String** containing the found groups.
Examples	Assume we have an URL that we want to break down to its elements: ```set aMailAddress = "support@e2ebridge.com"; set elements = aMailAddress.capture("(.*)@(.*)\.(.*)");``` This will result in an array `elements` having the array elements `["support", "e2ebridge", "com"]`.
